

1999 Multiple Indicator Cluster Survey

Executive summary

Most Filipinos know that children inherently have rights. The 1999 MICS finds that majority of women and caretakers of children can easily identify a child's right to have education.

This survey also suggests that significant advances have been achieved in the areas of elementary school participation rate, birth registration, and prenatal care of pregnant women.

However, the 1999 MICS indicates that government and private agencies should focus on the areas of micronutrient supplementation, consumption of iodized salt, early childhood education participation, child labor, and HIV-AIDS awareness.

Household population

- The 1999 MICS projects a total household population of 75.332 million with an almost equal number of males and females.
- Approximately 43 percent are children below 18 years old. Only six percent are senior citizens over 60 years old. Half of the total household population are Filipinos of productive ages 18 to 59 years old.

Education

- Majority (89%) of the population over age 10 years is literate. Around seven percent more are seen as moderately literate. There is an almost equal distribution of literate males and females. The urban population posts a higher literacy status of 94 percent.
- The literacy percentage declines from an average of 93 percent among those aged 15-34 to 70 percent among the population aged 65 and older.
- There are about 22 million children of school age (5-17 years old). Seventy-seven percent of these children (5-17 years old) are reportedly enrolled in school year 1999-2000. About 86 percent of children of primary school age (6-12) are attending school at the time of the MICS. There seems to be no significant difference between urban and rural school enrolment.
- Enrolment rate appears to dwindle as the school level progresses. Enrolment rate from grade one to grade six drops by almost 20 percent.
- Enrolment in pre-school education remains low. Only 15 percent of children aged three to five years are attending some form of organized early childhood programme.

Maternal and infant health care

- There are an estimated 19 million women in the reproductive ages 15-49. Approximately 93 percent of these women are literate. Fifty-five percent reside in urban areas.
- About 58 percent had given birth at least once. Ten percent of these mothers (1.96 million) gave birth in the year prior to the MICS. The mean age of these mothers is 28.
- Nine out of ten mothers reported that they made at least one visit to a health center with prenatal care facilities. On the average, these mothers made five visits. Almost half of them had their first consultation in the second three-month period of pregnancy. Most of these mothers held their first prenatal visit only in the fourth month.
- Nearly 84 percent of these mothers consulted a midwife, a doctor, and any other skilled health care provider for their prenatal check-up. In rural areas, more mothers (46%) turn to a midwife. Those in urban areas (33%) prefer going to a doctor.
- Both parents jointly decide where the delivery will take place. This is claimed by 46 percent of mothers who had live births in the year prior to the MICS.

- A trained “hilot” attended to 41 percent of these deliveries. The percentage is higher among mothers in rural areas (60%).
- Approximately 55 percent of women who gave birth in the year prior to the survey perceived that their babies were of average size when they were born. Results of the MICS significantly indicate that only six percent of these mothers actually had infants with low birth weight (less than 2.5 kg).
- Out of 119,000 mothers who gave birth to infants with LBW, only 26 percent admitted to having given the child iron supplement. Younger literate mothers (20-29 years old) would more likely give iron supplement to their children.
- Only 33 percent of all mothers who had given birth in the year prior to the MICS received Vitamin A supplement

Child health

- The 1999 MICS projects a total of 3.8 million children aged less than two years old. About 46 percent of these children were reportedly weighed on a regular basis.
- Out of 7.7 million children (1-4 years old), 36 percent received vitamin A supplement within the last six months prior to the MICS.
- Out of 9.4 million children (2-6 years old), 42 percent had received antihelminthics within the six months prior to the MICS.
- Out of 9.6 million children (0-4 years old), only 16 percent were diagnosed with acute respiratory infections (e.g. coughs). Sixty-four percent of those with ARI were treated at an appropriate medical center.

Salt iodization

- Only 22 percent of 14.6 million Filipino households consume adequately iodized salt. Households in urban areas (27%) are more prone to using iodized salt than those in rural areas (18%).

Birth registration

- The births of 84 percent of children below seven years old have been registered. Birth registration in urban areas is slightly higher than in rural areas. Across age, the lowest figure is at 77 percent among children less than a year old. No significant difference is recorded between boys and girls.

Awareness of the rights of the child

- Out of 32 million Filipinos who act as caretakers of children (below 18 years old), 83 percent know that children have rights and can identify at least one right.
- The right to education is the most frequently mentioned right for these caretakers (75%).
- Only two percent have recognized that children should be defended and given assistance by the government.

Living arrangements

- Four of five children still live with their parents.
- Approximately eight percent of 32 million children (less than 18 years old) are not residing with their parents.
- Approximately four percent (1.4 million) live away from their nuclear families. A child in this situation is most likely a teen-age girl who comes from a rural area.

Working children

- The 1999 MICS estimates a total of 22.5 million children who are 5-17 years old.
- Approximately, three million children (14%) are engaged in family-operated agricultural or business activities. Most of these children are boys and from rural areas.
- About 1.5 million children (5%) are working for someone other than a household member. One-fifth of working children receives payment in cash or in kind. Approximately half a million children (2%) render unpaid work. Again, most of these children are boys and from rural areas.
- Almost half of the total number of children who are 5-17 years old spend more than four hours a day doing domestic chores. More girls are reportedly doing household chores. More children in rural areas are in these situations.

HIV-AIDS awareness

- Out of 19 million women (15-49 years old), 92 percent have heard of AIDS.
- Most women are aware of the ways of preventing the transmission of HIV-AIDS from one person to another. Nearly 72 percent believe that avoiding multiple sex partners lessens the likelihood of transmission. Almost 55 percent say that the use of condom prevents the transmission of the virus. Sixty percent have identified that a drug abuser who indiscriminately uses an infected syringe can get infected with the virus. Almost 80 percent are aware that a pregnant mother with HIV-AIDS can transmit the virus to her child.
- Most women (70%) tend to disagree with the misconception that a healthy-looking person is immune from HIV-AIDS. However, only 40 percent are able to identify that getting the virus from mosquito bites is a misconception.
- Most women appear to exhibit discriminatory attitude toward people with HIV-AIDS. Around 62 percent think that a teacher with HIV-AIDS but is not physically sick should not be allowed to work. Close to 73 percent dispel the notion of buying food from a vendor with HIV-AIDS.
- The 1999 MICS focuses on the accurate identification of HIV prevention and misconceptions as basis for computing a person's sufficient knowledge of the disease. Only 2.4 of these women have correctly identified all these elements that are included in the MICS.
- Fifty-five percent know where to get an HIV-AIDS test. Six of ten women in urban areas are aware of this information. The figure is lower for women gathered from the rural clusters (48%). Younger women appear to be more aware of this information than those in the 40-and-above bracket.

Appendix A. Summary of indicators

Most Filipinos know that children inherently have rights. The 1999 MICS finds that majority of women and caretakers of children can easily identify a child's right to have education.

This survey also suggests that significant advances have been achieved in the areas of elementary school participation rate, birth registration, and prenatal care of pregnant women.

However, the 1999 MICS indicates that government and private agencies should focus on the areas of micronutrient supplementation, consumption of iodized salt, early childhood education participation, child labor, and HIV-AIDS awareness.

Household population

- The 1999 MICS projects a total household population of 75.332 million with an almost equal number of males and females.
- Approximately 43 percent are children below 18 years old. Only six percent are senior citizens over 60 years old. Half of the total household population are Filipinos of productive ages 18 to 59 years old.

Education

- Majority (89%) of the population over age 10 years is literate. Around seven percent more are seen as moderately literate. There is an almost equal distribution of literate males and females. The urban population posts a higher literacy status of 94 percent.
- The literacy percentage declines from an average of 93 percent among those aged 15-34 to 70 percent among the population aged 65 and older.
- There are about 22 million children of school age (5-17 years old). Seventy-seven percent of these children (5-17 years old) are reportedly enrolled in school year 1999-2000. About 86 percent of children of primary school age (6-12) are attending school at the time of the MICS. There seems to be no significant difference between urban and rural school enrolment.
- Enrolment rate appears to dwindle as the school level progresses. Enrolment rate from grade one to grade six drops by almost 20 percent.
- Enrolment in pre-school education remains low. Only 15 percent of children aged three to five years are attending some form of organized early childhood programme.

Maternal and infant health care

- There are an estimated 19 million women in the reproductive ages 15-49. Approximately 93 percent of these women are literate. Fifty-five percent reside in urban areas.
- About 58 percent had given birth at least once. Ten percent of these mothers (1.96 million) gave birth in the year prior to the MICS. The mean age of these mothers is 28.
- Nine out of ten mothers reported that they made at least one visit to a health center with prenatal care facilities. On the average, these mothers made five visits. Almost half of them had their first consultation in the second three-month period of pregnancy. Most of these mothers held their first prenatal visit only in the fourth month.
- Nearly 84 percent of these mothers consulted a midwife, a doctor, and any other skilled health care provider for their prenatal check-up. In rural areas, more mothers (46%) turn to a midwife. Those in urban areas (33%) prefer going to a doctor.
- Both parents jointly decide where the delivery will take place. This is claimed by 46 percent of mothers who had live births in the year prior to the MICS.

- A trained “hilot” attended to 41 percent of these deliveries. The percentage is higher among mothers in rural areas (60%).
- Approximately 55 percent of women who gave birth in the year prior to the survey perceived that their babies were of average size when they were born. Results of the MICS significantly indicate that only six percent of these mothers actually had infants with low birth weight (less than 2.5 kg).
- Out of 119,000 mothers who gave birth to infants with LBW, only 26 percent admitted to having given the child iron supplement. Younger literate mothers (20-29 years old) would more likely give iron supplement to their children.
- Only 33 percent of all mothers who had given birth in the year prior to the MICS received Vitamin A supplement

Child health

- The 1999 MICS projects a total of 3.8 million children aged less than two years old. About 46 percent of these children were reportedly weighed on a regular basis.
- Out of 7.7 million children (1-4 years old), 36 percent received vitamin A supplement within the last six months prior to the MICS.
- Out of 9.4 million children (2-6 years old), 42 percent had received antihelminthics within the six months prior to the MICS.
- Out of 9.6 million children (0-4 years old), only 16 percent were diagnosed with acute respiratory infections (e.g. coughs). Sixty-four percent of those with ARI were treated at an appropriate medical center.

Salt iodization

- Only 22 percent of 14.6 million Filipino households consume adequately iodized salt. Households in urban areas (27%) are more prone to using iodized salt than those in rural areas (18%).

Birth registration

- The births of 84 percent of children below seven years old have been registered. Birth registration in urban areas is slightly higher than in rural areas. Across age, the lowest figure is at 77 percent among children less than a year old. No significant difference is recorded between boys and girls.

Awareness of the rights of the child

- Out of 32 million Filipinos who act as caretakers of children (below 18 years old), 83 percent know that children have rights and can identify at least one right.
- The right to education is the most frequently mentioned right for these caretakers (75%).
- Only two percent have recognized that children should be defended and given assistance by the government.

Living arrangements

- Four of five children still live with their parents.
- Approximately eight percent of 32 million children (less than 18 years old) are not residing with their parents.
- Approximately four percent (1.4 million) live away from their nuclear families. A child in this situation is most likely a teen-age girl who comes from a rural area.

Working children

- The 1999 MICS estimates a total of 22.5 million children who are 5-17 years old.
- Approximately, three million children (14%) are engaged in family-operated agricultural or business activities. Most of these children are boys and from rural areas.
- About 1.5 million children (5%) are working for someone other than a household member. One-fifth of working children receives payment in cash or in kind. Approximately half a million children (2%) render unpaid work. Again, most of these children are boys and from rural areas.
- Almost half of the total number of children who are 5-17 years old spend more than four hours a day doing domestic chores. More girls are reportedly doing household chores. More children in rural areas are in these situations.

HIV-AIDS awareness

- Out of 19 million women (15-49 years old), 92 percent have heard of AIDS.
- Most women are aware of the ways of preventing the transmission of HIV-AIDS from one person to another. Nearly 72 percent believe that avoiding multiple sex partners lessens the likelihood of transmission. Almost 55 percent say that the use of condom prevents the transmission of the virus. Sixty percent have identified that a drug abuser who indiscriminately uses an infected syringe can get infected with the virus. Almost 80 percent are aware that a pregnant mother with HIV-AIDS can transmit the virus to her child.
- Most women (70%) tend to disagree with the misconception that a healthy-looking person is immune from HIV-AIDS. However, only 40 percent are able to identify that getting the virus from mosquito bites is a misconception.
- Most women appear to exhibit discriminatory attitude toward people with HIV-AIDS. Around 62 percent think that a teacher with HIV-AIDS but is not physically sick should not be allowed to work. Close to 73 percent dispel the notion of buying food from a vendor with HIV-AIDS.
- The 1999 MICS focuses on the accurate identification of HIV prevention and misconceptions as basis for computing a person's sufficient knowledge of the disease. Only 2.4 of these women have correctly identified all these elements that are included in the MICS.
- Fifty-five percent know where to get an HIV-AIDS test. Six of ten women in urban areas are aware of this information. The figure is lower for women gathered from the rural clusters (48%). Younger women appear to be more aware of this information than those in the 40-and-above bracket.

Missing data

To check the quality of the survey data, a look at the number of cases of missing information is necessary. Table 1 lists down the percentage of entries that have missing data. Only five items in the study yielded missing cases of one percent and less, namely: number of hours spent by working children doing household chores; grade/year level of children who are currently attending school; complete birth date of women (15-49) with live births; knowledge of women (15-49) on where to consult for HIV test.

Four percent of women (15-49) with a live birth in the year prior to the survey failed to indicate the birth weight of their infants. By international standards, this percentage is relatively negligible.

Response rates

In the 1999 MICS, a household pertains to a group of persons who share and take their meals together but live in separate and adjacent living quarters for convenience.

Of the 7,680 households selected for the 1999 MICS sample, 7,556 were completely interviewed. This yielded a high response rate of 98.4 percent. The response rates in both rural (99 percent) and urban areas (98 percent) were considerably high (Table 2).

In these households, 9,615 women aged 15-49 were identified as eligible for an interview. Of these, 9,424 were successfully interviewed, yielding a response rate of 98 percent. In addition, 4,705 children under age five were listed in the household questionnaire. Questionnaires were completed for 4,639 children for a response rate of 98 percent.

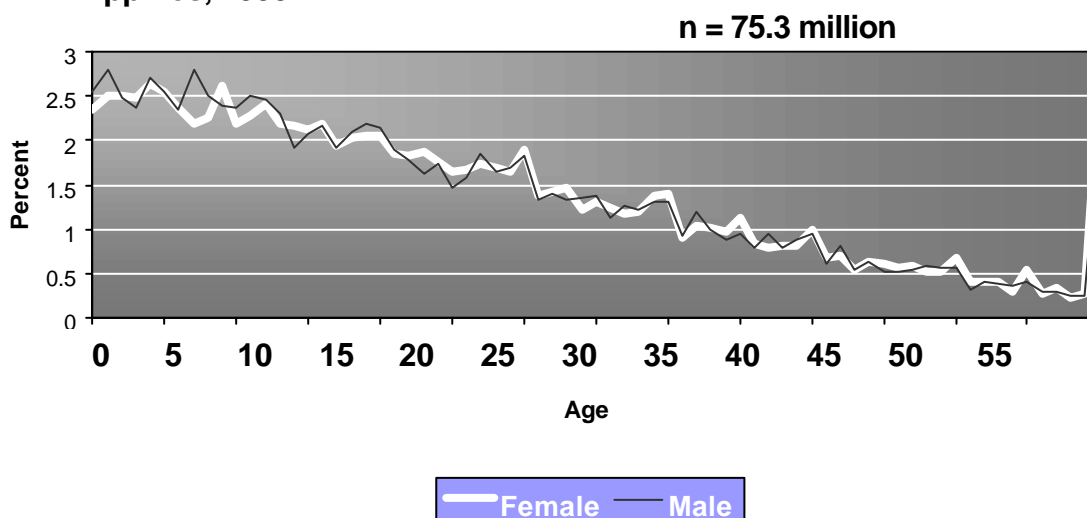

Age distribution

There are now about 75 million Filipinos.

Put ten Filipinos together in one room. Let this group be representative of the total projected population of 75.332 million. Four of them are children below 18 years old. Five are adults aged 18 to 59 years old. The last one is a senior citizen 60 years or older.

There appears to be no significant difference between the number of males and females, as shown in Table 3 and *Figure 1*. However, a cursory look at Table 4 will reveal that there are more males than females in the below 20 age group. This is a significant occurrence that may be used as a take-off point for checking the possibility of gender bias in selected indicators.

Figure 1.
Single year age distribution of the household population by sex, Philippines, 1999.

Characteristics of the household population

There are nearly 15 million Filipino households.

The 1999 MICS estimates a total of 14,583 million households. There are more households in rural areas than in urban centers. Almost 52 percent of the households (7,556 million) are rural and 48 percent (7,027 million) are urban. Table 5 presents the percent distribution of households in the 1999 MICS sample by background characteristics.

Most of the households have two to seven members. About 77 percent have at least one child of less than 18 years old. However, only 26 percent of these households have at least one woman aged 15-49 years old.

Women (15-49 years old)

A little over one-fourth of the total Filipino population are women ages 15-49.

There are an estimated 19 million women in these reproductive ages. Table 6 shows the characteristics of these women. Fifty-five percent of them reside in urban areas. Teen-age girls (15-19) comprise the greatest percentage of the sample at 20 percent. This percentage declines across age groups until age bracket of 45-49 at nine percent, as seen in *Figure 2*. Approximately 60 percent of women in the sample are currently married. The same can be said for the number of women who had ever given birth.

Figure 2.
Percent distribution of women (15-49 years old), Philippines, 1999.
n = 19.265 million

Children below 18 years old

Two-fifths of the Filipino population are children.

There are 32 million children comprising 43 percent of the population. Table 7 provides a description of these children. Boys (51%) slightly outnumber girls (49%). There are more children residing in rural areas (54%) than in urban areas (46%). Thirty-six percent of these children are below six years old.

Literacy

Nine of ten Filipinos can read and write a simple message.

For years, the Philippines has been noted for its high literacy rate. Literacy is defined as the ability of an individual to read and write. In the 1999 MICS, a literate person is someone who can easily read and write a simple message in any language or dialect. A moderately literate person can read and write but with difficulty. A person who cannot both read and write a simple message is illiterate.

The vast majority of the population over age 10 years is literate, as shown in *Figure 3*. Of the nearly 56.2 million Filipinos aged 10 years and older, approximately 90 percent are literate. About four million (7%) are seen as moderately literate. Only three percent are perceived as illiterate. There is an almost equal distribution of literate males and females, as indicated in Table 8.

Figure 3.
Percent distribution of literacy rate of Filipinos (10 years and older),
Philippines, 1999.
n = 56.2 million

More literate people come from urban areas. Of the total literate population, 55 percent reside in urban areas. The urban population has a higher literacy rate of 95 percent compared to 84 percent among those in rural areas. The literacy percentage declines from an average of 93

percent among those aged 15-34 to 70 percent among the population aged 65 and older. Illustrated in *Figure 4* is the literacy percentage of each age bracket.

Figure 4.
Literacy percentage per age bracket, Philippines, 1999.

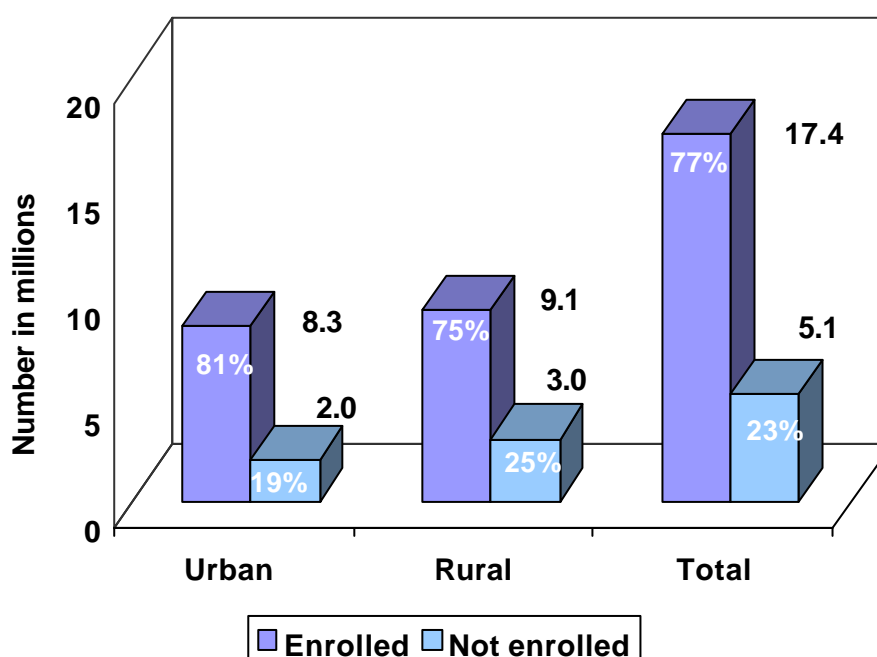

Basic education

Primary school enrolment rate in 1999 swelled by more than 10 percent of the 1996 level.

The 1999 MICS estimates about 22.525 million children (5-17 years old). Seventy-seven percent of them were reportedly enrolled in school year 1999-2000. About five million children (23%) were not attending school at the time of the 1999 MICS data gathering. [Table 9](#) shows the number of children attending school in urban and rural areas stratified by age and sex. Although there seems to be more children who are attending school in rural areas (9.1 million) than in urban areas (8.3 million), the figure only represents 75 percent of all rural children. As seen in *Figure 5*, enrolment rate in urban areas is notably higher at 81 percent.

Figure 5.
Proportion of children (5-12) who were enrolled in school year 1999-2000, Philippines, 1999.

A major goal for basic education is to provide equal opportunities to boys and girls. The survey reveals that there appears to be no gender bias against girls. This suggests that more girls are now being given the chance to get educated in a formal school environment.

The enrolment rate in primary (elementary) education is computed at 86 percent of the population of children (6-12). This value is ten percent more than the recorded rate in the 1996 MICS as illustrated in *Figure 6*.

The highest enrolment record is in the grade one level. Eighteen percent of all elementary students are grade one pupils. The mean age of grade one students is seven. However, enrolment rate appears to dwindle as the school level progresses. Enrolment in the sixth grade is smaller by almost 10 percent than the grade five level record. Refer to Table 10 for the details.

Figure 6.
Primary school participation rate, 1996 and 1999 MICS.

The 1999 MICS, however, was not designed to ascertain the cohort survival rate or the number of children who eventually reach grade five.

Two major reasons are noted why children do not go to school. These are the high cost of education and the seemingly lack of interest from children themselves. The lack of personal interest appears more apparent among children in rural areas. It is the foremost reason provided

for almost 754,000 (15%) children. In urban areas, the high cost of education has kept 627,000 (12%) children out of school (Table 11.)

Early childhood education

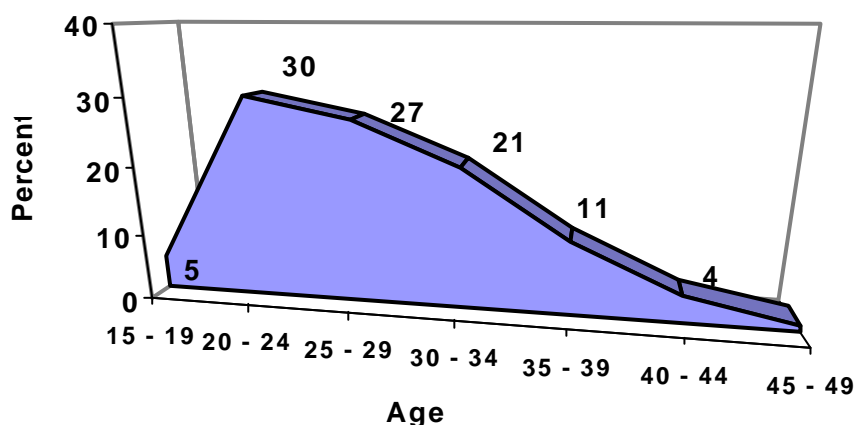

Very few children go to pre-school and day care centers.

The early years of a child's life, 06 years old in particular, serve as the foundation for learning throughout life. Hence, the Early Childhood Care and Development (ECCD) programme becomes one of the most critical support strategies for achieving education for all and education for life.

However, the 1999 MICS findings indicate that enrolment in pre-school education still remains wanting. Only 15 percent of approximately 7.6 million children aged three to six years old attended some form of organized early childhood programme in pre-school, nursery, and day care centers at the time of the survey.

There are slightly more children in urban areas enrolled in an early childhood education programme than in rural areas. Table 12 also indicates that there are more young girls than boys who attended pre-school at the time of the 1999 MICS.

Figure 7.
Percentage distribution of women with live births, Philippines, 1999.
n = 1.955 million

Maternal health care

More Filipino women are learning to seek proper maternal health care.

The 1999 MICS projects an estimate of 19 million women of reproductive ages 15-49. About ten percent or nearly two million of these women had live births in the year prior to the survey (Table 13). The mean age of these women is 28. *Figure 7* shows the percentage distribution of these live births across ages.

An important World Summit Goal that addresses the rights of mothers is the access of all women to proper prenatal care and obstetric care. Two key indicators of this goal are the proportion of women who had at least one visit to skilled health personnel and the proportion of births attended by skilled health personnel.

Prenatal care

Nine of ten pregnant women seek health care.

On the average, pregnant mothers made five visits to a health center for prenatal check-up. Almost half of them had their first consultation in the second three-month period of pregnancy. Most of them scheduled their first prenatal visit only in the fourth month. Details of this information are outlined in Tables 14-15.

About 45 percent of mothers in urban areas reported to have made their first prenatal visit in the critical first period of pregnancy. In rural areas, 52 percent of mothers had theirs in the second period.

Table 16 shows the type of personnel who attended to mothers during their prenatal care consultations. In rural areas, more mothers (46%) turned to a midwife. Those in urban areas (33%) preferred going to a doctor.

Respondents were also asked what are the particular symptoms that they could identify that would prompt them to seek health care during pregnancy. The most frequent response is vaginal bleeding. A more detailed outline is shown in Table 17.

Childbirth care

Two of five live births are assisted by a trained *hilot*.

The word *hilot* is a Filipino term for “massage” when used as a treatment for sore and fracture. It is also used to refer to people who assist in the delivery of babies without a formal educational background in obstetrics.

This practice is most prevalent in rural areas with 58 percent of all live births assisted by a trained *hilot*. Despite the preference for doctors during prenatal care, the data from urban mothers suggest a preference for midwives in the delivery of babies. Almost 44 percent of live births in urban areas were delivered by a midwife (Table 18).

Women should be empowered by giving them informed choices about their own health. About 46 percent of women who had live births in the year prior to the 1999 MICS said that the decision to where the baby would be delivered was jointly made with their husbands. Similar responses are observed from both the urban and rural samples as indicated in Table 19.

Low birth weight

There are only a few reported cases of low birth weights.

Another indicator set at the World Summit for Children is the reduction of low birth weight rate to less than 10 percent of all live births. An infant with LBW weighs less than 2.5 kg. Babies with LBW are at a higher risk of a serious illness or death. *Figure 8* presents the percentage distribution of LBW births among women. (Refer also to Tables 20-21.) Surprisingly, the cases of infants with LBW among teen-age mothers or those with high-risk pregnancies are minimal.

Figure 8.
Percentage distribution of women with LBW infants, Philippines, 1999.
 n = 119,000

Respondents were asked about their opinions on the size of their babies at birth. If available, information about the child's actual birth weight was taken from existing documents such as the child's birth certificate, vaccination cards, and others.

Approximately 17 percent of women who gave birth in the year prior to the 1999 MICS thought that their babies are either very small or smaller than average. Most of these mothers (55%) believed that their newly born infants are of average weight. After being tabulated against registered birth weights, results of the survey indicate that only six percent of these mothers actually had infants with LBW. This is found in Table 22.

Infant and child health care

Children first!

This is a cry that resounds across the country. Children should be given utmost attention especially in health and nutrition programmes. The Department of Health and its support agencies have been taking the lead to quell malnutrition in the country. Through programmes like the National Immunization Day and the Preschoolers' Health Week among others, the DOH has focused on core and critical areas such as immunization, growth monitoring, micronutrient supplementation, food fortification, and salt iodization.

Critical in all nutrition programmes is the focus on micronutrients such as vitamin A, iron, and iodine. Deficiency in these micronutrients leads to increased infant, child, and maternal mortality and morbidity rates.

Vitamin A supplementation

Vitamin A supplementation has gone low in 1999.

In the 1999 MICS, questions were formulated to evaluate vitamin A and iron supplementation of mothers and children. Vitamin A coverage is one of the most important components of child and maternal survival programs. It is essential for the normal functioning of the immune system. It also prevents night blindness and susceptibility to other infections.

Out of about two million mothers who had given birth in the year prior to the 1999 MICS, only 33 percent received Vitamin A supplement ([Table 23](#)). A key indicator toward eliminating vitamin A deficiency is the proportion of mothers who receive a high-dose vitamin A supplement before the infant is two months old. Based on the 1999 MICS, this indicator refers to only 25 percent of these mothers.

For children ages one to four years old, almost 60 percent received vitamin A within the period covering one year before the 1999 MICS. Approximately 27 percent did not receive a dose of vitamin A at all. [Table 24](#) also looks at the time period when a child received vitamin A.

Iron

Few infants with low birth weights receive iron supplement.

Iron deficiency anemia (IDA) is a condition in which the concentration of hemoglobin in a person is below the normal level. Hemoglobin is the substance in blood that carries oxygen. Anemic pregnant women are prone to deliver babies with LBW. Children with IDA have short attention span, reduced ability to learn and are usually irritable.

In the 1999 MICS, out of 119,000 mothers who had given birth to children with LBW, only 12 percent reported to have given the child iron supplement. The figure is lower at 7 percent for women in urban areas. [Table 25](#) provides a detailed account of the proportion of children with LBW who were given iron supplement and the age of their mothers.

Figure 9.
Vitamin A coverage of children (1-4 years old),
Philippines, 1999.
n = 7.7 million

Salt iodization

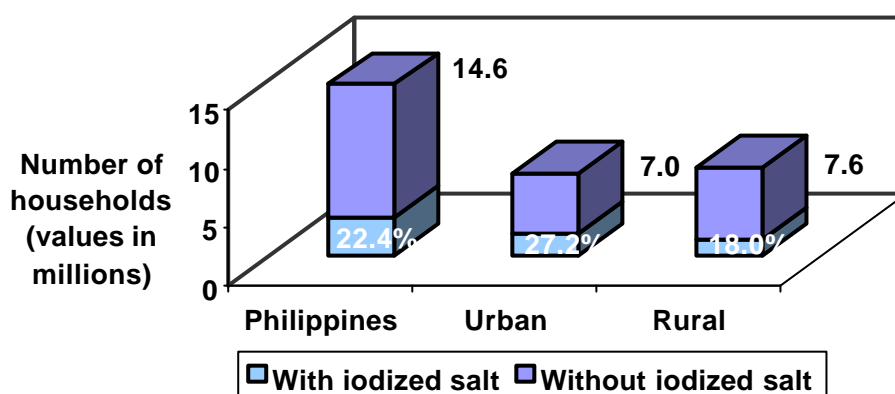

Consumption of iodized salt is still low.

Iodine deficiency in pregnant women causes spontaneous abortion, still births, impaired fetal brain development and infant deaths. An iodine deficiency disorder (IDD) also causes mental retardation and neurological complications in children.

Figure 10.

Proportion of households consuming iodized salt, Philippines, 1999.

n = 14.6 million

In 1995, the Philippine government embarked on a salt iodization program as a long-term measure to prevent IDD. Republic Act 8172 or “An Act Promoting Salt Iodization Nationwide and For Other Purposes” aimed for universal salt iodization use nationwide by 2000. The law requires all food grade salt to be iodized. It also mandates all salt traders to make iodized salt available to all Filipinos.

Despite massive campaign on the use of iodized salt, consumption in the Philippines remains low. The 1999 MICS findings indicate that out of 14.583 million households, only 22 percent use iodized salt.

With tool kits provided by the DOH, field researchers tested the presence of iodine in cooking and table salt used in Filipino households. Households in rural areas (18%) are less prone to consuming iodized salt than those in urban areas (27%). *Figure 9* shows the proportion of urban and rural households that consume iodized salt. Refer also to [Table 26](#).

Acute respiratory infections (ARI)

Three of five children with ARI have received proper medical treatment.

Acute respiratory infections (ARI), particularly pneumonia, are one of the leading causes of child deaths. In the 1999 MICS questionnaire, children with ARI are defined as those who had an illness with a cough accompanied by rapid or difficult breathing and whose symptoms were

due to a chest problem, a clogged nose, or both. Included also were questions inquiring whether the caretaker was aware of the source of the problem and if treatment was sought.

Sixteen percent of children under five years old had an acute respiratory infection in the two weeks prior to the survey. Approximately 64 percent of these children were taken to an appropriate health provider. Treatment was mostly administered in health centers. Tables 27-28 provide this information.

Anthelmintics

More children in rural areas have been dewormed.

In the 1999 MICS, caretakers were asked if the child (2-6 years old) was given anthelmintics medicine in the six months prior to the survey. Table 29 presents the proportion of these children who received deworming medicine. Out of 9.4 million children, approximately 42 percent had been dewormed, with more children in rural areas (45%) than in urban areas (40%) receiving such medication.

Weight monitoring

The weights of children are not regularly monitored.

Post-natal infant care includes the monitoring of the child's growth in terms of height and weight. In the 1999 MICS, focus was given to weight monitoring of children. Table 30 presents the proportion of children (0-1 year old) who have been weighed regularly after birth. More children were not regularly weighed after birth. Out of 3.8 million children, only 46 percent had been weighed on a regular basis.

Children's Rights

Awareness of CRC

Most Filipinos know that children inherently have rights.

Table 31 shows that out of 35 million Filipinos who act as caretakers of children below 18 years old, 84 percent know that children have rights and can identify at least one right. Awareness is higher among respondents from urban areas (88%) than those in rural areas (81%).

Table 32 provides a list of the most commonly identified children's rights. The right to education is the most frequently mentioned right for these caretakers (67%). It should be noted that only two percent have recognized that children should be defended and given assistance by the government.

Birth registration

Four of five children below seven years old have official birth certificates.

The civil code and other laws in the country are concerned with the provisions of legal or civil rights to the citizens. The government therefore is the sole provider of such rights to its citizenry. Proof of one's claim to such rights depends much on official registration. A person's birth is one of the vital events for official registration. The official document of such recording of birth events is the birth certificate.

Thus, the 1999 MICS included a module that would determine the extent of birth registration of children below seven years old. Out of 13 million children in this age bracket, 84 percent have their births registered, as shown in Table 33. Birth registration in urban areas (87%) is slightly more frequent than in rural areas (81%). Across age, the lowest figure is at 77 percent among children less than a year old. No significant difference is recorded between boys and girls.

Respondents were also asked why the birth of the child was not registered. The cost of registration was one of the most frequently mentioned reasons. Other responses are indicated in Table 34.

Orphanhood and living arrangements

Four of five children still live with their parents.

One of the most basic rights of children is to have a family who will love and care for them. This involves having a home they can call their own. Children who are orphaned or living away from their parents may be at increased risk of impoverishment, discrimination, denial of property rights and rights to inheritance, various forms of abuse, neglect, and exploitation of their labor or sexuality. Thus, monitoring the level of orphanhood and the living arrangements of children assists in identifying those who may be at risk and in tracking changes over time.

Table 35 provides the proportion of children below 18 years old by their living arrangements. This indicates whether a child is living or not with both parents. Out of almost 32 million children, close to 84 percent are still living with both parents.

There are about five percent who live with only one parent even if the other parent is still alive. About eight percent are not living with both parents with only less than one percent considered as orphans. It should be noted that only 10 percent of these children living with both parents are aged 15-17 years old. This indicates that more teenagers are living away from home.

Table 36 offers a look at the proportion of children below 18 years old who live away from home by age group and sex. Of the 1.4 million children reportedly living away from their homes, there are more girls (56%) than boys (44%). This incidence is higher in the cases of children in rural areas who comprise 57 percent of the total number of children living away from their homes.

Working children

More boys are involved in paid and unpaid work. More children in rural areas are engaged in such work. More girls perform household chores for more than four hours in a day.

Child labor deprives children of their childhood. It endangers their health and education. It takes away all their chances to discover, explore, and carry out the promise of good life. It is therefore imperative to check the extent to which children work and the type of work in which they participate. Children who are working are less likely to attend school and more likely to drop out from school. Working conditions for children are often unregulated with few safeguards against potential abuse and exploitation. In addition, many types of work are ultimately hazardous to children.

In the 1999 MICS, respondents were asked whether the child in the household performed any kind of paid or unpaid work for someone who is not a member of the household. Another question inquired if the child was involved in any economic activity, whether agricultural or not, that is operated by a member of the child's family. The questionnaire also included a query on the amount of time that a child spends doing domestic chores.

Responses to these particular questions were calculated separately to determine the number of children who may be considered currently working. A child who is currently working may either perform any of the following:

- a. Paid or unpaid work for someone who is not a member of the household;
- b. More than four hours of housekeeping chores in the household; or
- c. Other work in family-operated activities.

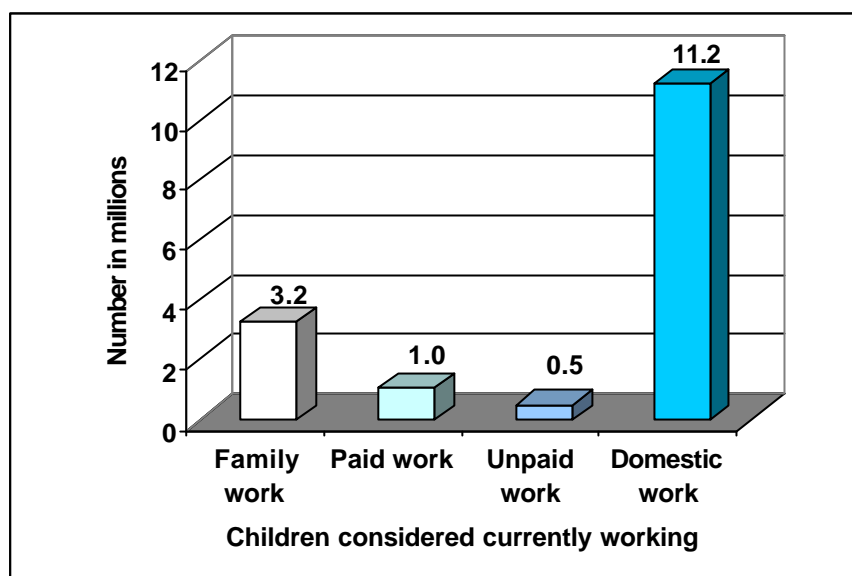

Table 37 presents in detail the number of children who are considered currently working. About 45 million children are said to be working for a family member or for someone else. Almost half of all children have done domestic chores for four or more than four hours in a day.

The survey estimates that about one million children aged 5-17 years old (5%) are engaged in paid work. Payment may either be in cash or in kind. Two percent (478,175) participate in unpaid work for someone other than a household member. There are more boys who belong to these two categories. Whether given a remuneration or not, children in rural areas are more likely working for someone who is not a member of their households.

Approximately 3.2 million children are doing family work. Children in rural areas comprise 65 percent of all children who work in other family-operated activities, such as farming, fishing, manning retail stores or market stalls. More children aged 10-14 are involved in these kinds of work.

About 11.2 million children are said to be doing domestic work for more than four hours in a day. Of these number, 53 percent are girls. Around 60 percent of these children come from rural areas. Again, children in the 10-14 age group are more likely doing household chores than older children.

Figure 11.
Proportion of children (5-17) who are considered "working", Philippines, 1999.

Children who live away from their homes commonly find themselves employed in service-oriented jobs. Close to 1.2 million children (5-17) live away from home. As seen in [Table 38](#), about 814,000 children (69%) are working either as household helper, food server, retail store attendant, or other jobs that provide service to clients. There are more girls doing such jobs. As may be expected, there are more children in urban areas who find themselves in an industrial type of work. Those engaged in agricultural work are more likely to be boys living in rural areas.

HIV-AIDS

Awareness

Most women have heard of AIDS but only few have sufficient knowledge about it.

In the 90s, there has been a widespread campaign on the nature of the human immunodeficiency virus (HIV) and its full-blown state called the acquired immune deficiency syndrome (AIDS). Although the rate of HIV-AIDS infection has not yet reached catastrophic level, information programmes have continued to educate people.

Respondents in the 1999 MICS were given a set of statements that pertain to different issues concerning HIV-AIDS such as its ways of prevention, modes of transmission, and discrimination against people with HIV-AIDS.

About 92 percent of women (15-49 years old) in the MICS are aware of HIV-AIDS. More women from urban than rural areas have heard of HIV-AIDS. The percentage is higher in urban areas (94%) than in rural areas (88%). Younger women (15-24) appear to be more knowledgeable of the virus. (See [Table 39](#).)

More than 50 percent of females of reproductive ages can properly identify ways to prevent the transmission of the virus from one person to another as shown in Table 40. Seventy-two percent agree that having only one uninfected sex partner can prevent HIV transmission. A little over 50 percent believe that using a condom every time one has sex can prevent transmission.

Table 41 contains the degree of agreement of respondents to statements on possible modes of transmission of HIV from one person to another. Sixty percent are aware that the virus can be transmitted with the use of an infected syringe. Close to 80 percent agree that a pregnant mother with HIV can infect the child.

Most women (70%) tend to disagree with the misconception that a healthy looking person cannot be infected with the virus. However, only 40 percent are able to identify that getting the virus from mosquito bites is a misconception. (Table 42.)

The 1999 MICS findings also suggest that women tend to exhibit discriminatory attitudes toward persons with HIV-AIDS. When asked if a teacher with HIV-AIDS should be allowed to work, approximately 62 percent of these women disagreed with the statement. About 73 percent dispel the idea of buying food from a vendor afflicted with HIV-AIDS. These are shown in detail in Table 43.

A woman who has sufficient knowledge about HIV-AIDS is someone who knows the two ways to prevent transmission and has correctly identified the two misconceptions on HIV-AIDS mentioned above. Only two percent of the female respondents gave such accurate responses. (Table 44).

Some 55 percent meanwhile know of a place where they can get tested for HIV-AIDS. As seen in Table 45, women in urban areas are more likely aware of a place than those in urban areas. Older women are less likely familiar with a place where HIV test is available.

Table 1.
Percentage of cases of missing information for selected questions, Philippines, 1999.

Indicator	Reference population	Percent missing
Grade/year of education currently attending	Children (5-17) currently attending school	0.04
Number of hours worked	Working children (5-17)	0.59
a. Outside the household		0.07
b. Household chores		0.25
c. Family-operated business		0.56
Complete birth date	Women (15-49) with a live birth	0.38
Knowledge on the place to test for HIV	Women (15-49) who have heard of HIV-AIDS	0.27
Complete birth weights	Children (0-6)	1.07
Birthweight of infants	Women (15-49) with a live birth in the last 12 months	3.94
